1 Introduction

AECOM was commissioned by the London Borough of Lewisham to install and maintain a network of NO₂ diffusion tubes to assess the spatial variation of nitrogen dioxide (NO₂) concentration within the Borough. The diffusion tube network comprises of 34 NO₂ diffusion tubes at 32 locations. One of these locations is a triplicate site and the remaining locations are single sites. The diffusion tubes were exposed for periods of between 4 and 5 weeks in accordance with the UK NO₂ Survey Timetable. The results of the survey provide Lewisham Borough Council with valuable monitoring data for use in their Local Air Quality Review and Assessment (LAQM) process.

This report outlines the results of the survey for January 2015 to December 2015, inclusive. The spatial variation in NO₂ concentration throughout the Borough is discussed and the annual mean values for each location are compared against the annual mean objective for NO₂ to indicate locations that may be likely to exceed the objective. Monthly concentrations are examined for evidence of seasonal trends.

Capabilities on project:
Environment

2 Legislative Background

Limit values and air quality objectives for nitrogen dioxide and oxides of nitrogen (NO_x) were set out in the First Daughter Directive (1999/30/EC) and subsequent revisions. An annual mean NO₂ objective was set at 40 µg/m³ to be achieved by 1st January 2010. A 200 µg/m³ hourly mean standard not to be exceeded more than 18 hours per year was also outlined, to be achieved by the same compliance date. These objectives were reiterated in the 2008 Directive on ambient air quality and cleaner air for Europe (2008/50/EC).

The UK has published its own Air Quality Strategy¹, which detailed the UK's position on nitrogen dioxide. The UK air quality objectives differ from the European objectives only in their compliance dates; the UK objectives were to be achieved by the end of 2005. European and UK air quality objectives have also been set for oxides of nitrogen for the protection of vegetation and ecosystems. A summary of the principal air quality objectives for NO₂ and NO_x is given in Table 1.

Table 1 UK and EU Air Quality Objectives for NO₂ and NO_x

Pollutant	UK Air Quality Objectives		
	Standard / Concentration	Measured as	Date to be achieved by and maintained thereafter
Nitrogen Dioxide	200 µg/m ³ not to be exceeded more than 18 times a year	1 Hour Mean	31.12.2005
	40 µg/m ³	Annual Mean	
Nitrogen Oxides (for the protection of vegetation)	30 µg/m ³	Annual Mean	31.12.2000
	EU Air Quality Objectives		
	Standard / Concentration	Measured as	Date to be achieved by and maintained thereafter
Nitrogen Dioxide	200 µg/m ³ not to be exceeded more than 18 times per year	1 Hour Mean	1 January 2010
	40 µg/m ³	Annual Mean	
Nitrogen Oxides (assuming as nitrogen dioxide)	30 µg/m ³	Annual Mean	19 July 2001

3 Monitoring Methodology

3.1 Description of Network

The Lewisham Diffusion Tube Network has been maintained by AECOM since January 2011. In 2011, the network consisted of 47 locations, in which one of these was a triplicate co-located site at the automatic monitoring stations in New Cross Road and the remaining were single sites, using a total 49 diffusion tubes. In 2012, the network was reduced to 34 diffusion tubes at 32 locations, comprising of single tubes at 31 locations and triplicates co-located at the New Cross Road continuous monitoring station. During 2015, diffusion tubes throughout the Borough have been deployed and collected at 4 to 5 weeks intervals in accordance with the UK NO₂ Diffusion Tube calendar².

The locations of the diffusion tubes are geographically illustrated in Appendix A.

3.2 Procedures and Site Changes

All diffusion tubes used in the network were stored in a refrigerator prior to deployment and after collection to reduce the possibility of degradation of the chemicals involved. Tubes subject to contamination (e.g. spider webs, foreign bodies, etc.) or vandalised have also been excluded from the final dataset.

In January 2015, the diffusion tube at Lawn Terrace (LWS 016) was moved to Montpelier Vale, on a lamppost outside the Aqua restaurant, for the start of the 2015 annual monitoring period.

3.3 Tube Preparation, Analysis and Laboratory QA/QC

The diffusion tubes were supplied and analysed by Gradko International Ltd, using a 50% triethanolamine (TEA) in acetone method. Gradko participates in the AIR Proficiency Testing (PT) scheme for diffusion tubes, operated by LGC Standards and supported by the Health and Safety Laboratory (HSL), which provides a Quality Assurance / Quality Control (QA/QC) framework for local authorities carrying out diffusion tube monitoring as a part of their local air quality management process. The percentage of results submitted from Gradko International Ltd which were subsequently determined to be satisfactory was 100% for all tests in AIR-PT Rounds AR001-AR010 (April 2014 - November 2015)³.

3.4 Factors Affecting Diffusion Tube Performance

NO₂ diffusion tubes are an indicative monitoring technique, as they do not offer the same accuracy as the reference method for NO₂, the automatic chemiluminescent analyser. NO₂ diffusion tubes are affected by several factors, which may cause them to exhibit bias relative to the reference technique.

Over-estimation may be attributed to one of the following three interfering factors:

- The shortening of the diffusive path length caused by the wind;
- The blocking of UV light resulting in reduced NO₂ photolysis in the tube; and
- The interference effects of peroxyacetyl nitrate (PAN).

Under-estimation can be caused by the following factors:

- Increasing exposure period, and is thought to be due to degradation of the absorbed nitrate with time;
- Insufficient extraction of nitrite from the meshes;
- The photochemical degradation of the triethanolamine-nitrite complex by light, although this is minimised by the use of opaque end-caps; and

Capabilities on project:
Environment

- The solution used. For example, 50% solution of TEA in water has been reported to lead to comparatively reduced NO₂ uptake.

There are a number of additional factors that may also affect diffusion tube performance including time of the year, the exposure setting (i.e. sheltered or open sites), the proximity to roads, the preparation method and analytical laboratory used, the exposure concentration and the ratio of NO₂ to NO_x.

3.5 Data Validation and Data QA / QC

Validation of diffusion tube readings is vital to ensure public confidence in the measurements produced. Validation is achieved through the following steps described in sub-sections below.

3.5.1 Blanks

The laboratory reserved a set of diffusion tubes for use as laboratory blanks for each dispatches of tubes to the user. These are kept in sealed containers in a refrigerator and analysed with the exposed tubes to provide a measure of nitrite concentration on unexposed tubes.

One travelling blank was taken to site during each of the monthly changeovers. These tubes accompany the user during tubes changeover but are not themselves exposed. The purpose of using field blanks is to identify possible contamination of the tubes during transportation or in storage by the user.

Laboratory and field blanks were routinely screened by AECOM to ensure quality of data. Neither the laboratory blanks nor the travel blank results were subtracted from the results of exposed tubes, in accordance to the Local Air Quality Management Technical Guidance (LAQM.TG(09))⁴ and the Diffusion Tube Practical Guidance.

3.5.2 Rejection of Diffusion Tube Results

Diffusion tube results obtained for each month were checked to meet the following criteria for inclusion in the final dataset:

- Correct calculation of exposure hours;
- Concentrations less than 3 µg/m³ were rejected as these concentrations are unlikely to occur in an urban area.
- Concentrations at the high end were not routinely rejected unless good evidence can be shown to prove the spurious results.
- Exposure records were checked for possible explanation of any unusual results (e.g. foreign objects, bonfires, pollution episodes, construction works, tampering, etc.).
- For triplicate site, diffusion tube that exhibits poor precision (>20%) was excluded from the final dataset. For single sites, professional judgement was used to accept or reject the results based on observations made during site visits.

3.5.3 Bias Adjustment Factor

Diffusion tube monitoring is indicative and does not offer the same accuracy as the reference method for monitoring NO₂ i.e. using an automatic chemiluminescent analyser. Several factors could affect NO₂ concentrations measured with diffusion tubes, which may cause them to exhibit bias (over-read or under-read readings) relative to the reference method (see Section 3.4). To correct this bias, comparison of the NO₂ concentration as measured by diffusion tubes is made with continuous monitoring data to derive a bias-adjustment factor.

Bias adjustment factor can be obtained using the Nitrogen Dioxide Diffusion Tube Bias Adjustment spreadsheet⁵, which is updated periodically and collates the bias-adjustment factors obtained in co-location studies conducted

⁴ Defra, Local Air Quality Management Technical Guidance LAQM.TG(09), 2009.

⁵ Defra, National Diffusion Tube Bias Adjustment Factor Spreadsheet (Version 03/16). Available at <http://laqm.defra.gov.uk/bias-adjustment-factors/national-bias.html>

Capabilities on project:
Environment

nationally. It can also be derived locally through co-location of diffusion tubes with automatic analysers and compared the results obtained from both methods of monitoring.

Further details of the monitoring sites used and the derivation of the factor can be found in Appendix B and Appendix C. The local bias factor was applied to all diffusion tube results in the period unless indicated otherwise.

3.6 Site Designations

3.6.1 Site Designations

The designation of site types is used to compare different locations statistically. Sites were categorised as kerbside, roadside, near road (intermediate) and urban background sites according to the definitions given in Defra's Local Air Quality Management Technical Guidance (TG.16), April 2016⁶. These definitions are reproduced in Table 2 below.

Table 2 Site Type Designation Criteria

Type	Definition
Urban Centre	An urban location representative of typical population exposure in towns or city centres, for example, pedestrian precincts and shopping areas.
Urban Background	An urban location distanced from sources and therefore broadly representative of city-wide background conditions, e.g. urban residential areas. For example: > 50m from any major source of NO ₂ , such as multi-storey car parks; > 30m from any very busy road (> 30000 vehicles per day); > 20m from any busy road (10000 – 30000 vehicles per day); > 10m from any main road (quiet roads e.g. within residential estates are acceptable; and > 5m from any area where vehicles are likely to be idling.
Suburban	A location type situated in a residential area on the outskirts of a town or city
Roadside	A site sampling typically 1-5m of the kerb of a busy road (can be up to 15 m from kerb in some cases)
Kerbside	A site sampling within 1m of the kerb of a busy road
Industrial	An area where industrial sources make an important contribution to the total pollution burden
Rural	An open countryside location, in an area of low population density distanced as far as possible from roads, populated and industrial areas
Other	Any special source-orientated or location category covering monitoring undertaken in relation to specific emission sources such as power stations, car-parks, airports or tunnels

Capabilities on project:
Environment

4 Results and Discussion

4.1 Data Capture

Data capture rates for the Lewisham Diffusion Tube Survey Network during 2014 were high, achieving an overall average of 96% for all site types. The lowest data capture for any site was 83% (2 months missing of out 12), which was reported at L2 (Bronze Street), L6 (Le May Avenue), L12 (Montague Avenue), SCH13 (Christ Church School, Perry Vale) and LWS 007 (New Cross AQM). There were 21 sites with 100% data capture.

Sites recording lower than 100% data capture were as a result of tubes being stolen, clips being vandalised or data not being included in the final dataset (see Section 3.5.2).

4.2 Bias Adjustment

4.2.1 Local Bias Adjustment Factor

The co-location site annual mean NO₂ concentrations measured by the diffusion tubes and the continuous monitors are displayed in Table 3.

The AEA Diffusion Tube Precision Accuracy Bias Spreadsheet⁷ tool was used to calculate the local bias adjustment factor for the co-location site. Continuous monitoring data was sourced from the London Air Quality Network (LAQN) website⁸. Further details can be found in Appendix C.

The complete diffusion tube results without the application of a bias adjustment factor can be found in Appendix B.

Table 3 Comparisons of Diffusion Tube Measurement and Continuous Monitors at Co-located Site

Site Name	2015 Annual Mean NO ₂ Concentration (µg/m ³)	
	Unadjusted Diffusion Tube	Continuous Monitor
Lewisham – New Cross	48.9	48.3

Monthly readings from the diffusion tubes were compared with concentration at Lewisham New Cross (Figure 1). An average bias adjustment factor of 1.02 was obtained. However, in calculating the local bias adjustment factor, it was clear that during the first three months, the monthly mean NO₂ concentrations reported by the automatic monitor (New Cross AQMS) were much greater than the monthly mean diffusion tube NO₂ concentrations, in contrast to the rest of the year when the diffusion tube NO₂ concentrations were greater than those from the AQMS. At locations close to sources of NO_x such as roadside and kerbside sites, within-tube chemical reactions of NO and O₃ have been found to result in over-reading in relation to reference method⁹, and therefore the results shown in Figure 1 only resemble the expected pattern from April onwards.

4.2.2 National Bias Adjustment Factor

Although the local bias adjustment factor is greater than the local factors derived in recent years, it was recommended that the bias adjustment factor obtained from national co-location studies¹⁰ be calculated, due to the contrast between the ratio of diffusion tube to AQMS concentrations for the first 3 months, compared to the rest of the year (as shown in Figure 1). The national bias adjustment factor for 2014 is 0.95 for the laboratory and preparation method, based on 9 studies (spreadsheet version 03/16).

Capabilities on project:
Environment

4.3 Annual Mean NO₂ Concentrations

The mean NO₂ concentration over the whole network during 2015 was 37.0 µg/m³ or, after applying a local bias adjustment of 1.02, 37.7 µg/m³. The mean concentration calculated using the national bias adjustment factor was 35.1 µg/m³; below the annual mean NO₂ objective of 40 µg/m³. The maximum annual mean NO₂ concentration was measured at the LWS017 site at 9 Baring Road (58.6 µg/m³ using the co-location study bias adjustment factor, or 54.6 µg/m³ using the national bias adjustment factor). The second highest annual mean NO₂ concentration was measured at LWS016 at Montpelier Vale (57.1 µg/m³ – co-location study bias adjusted or 53.2 µg/m³ – national bias adjusted). LWS017 and LWS016 are both roadside sites.

Table 4 Annual Mean NO₂ Concentration (Bias Adjusted), 2015

Site Type	Annual Mean NO ₂ Concentration (µg/m ³)		
	Raw	Bias Adjusted, using New Cross Co-located Tubes (Factor = 1.02)	Bias Adjusted, using National Bias Adjustment Factor (Factor = 0.95)
All Sites	37.0	37.7	35.1
Roadside	42.6	43.5	40.5
Urban Background	28.7	29.3	27.3

4.3.1 Comparison with Limit Values and Objectives

The air quality objectives and limit values of relevance to NO₂ in the UK are detailed in Section 2. The results in Table 4, obtained after applying the co-location study adjustment factor, indicate that the annual mean NO₂ objective of 40 µg/m³ was not generally exceeded within the diffusion tube network during 2015. However, from Appendix B, it can be seen that bias-adjusted annual mean NO₂ concentrations, obtained after applying the co-location adjustment factor, were greater than 40 µg/m³ at 14 of the 32 diffusion tube locations. Similarly, results based on the national bias adjustment factor show that 12 sites exceeded the NO₂ annual mean objective. These results may be partly due to the fact that concentrations at urban background sites were often considerably below the annual mean objective, whilst roadside sites generally exceeded the annual mean objective.

A report issued by Air Quality Consultants¹¹ analysed the relationship between annual mean and hourly mean NO₂ concentrations, concluding that locations where the annual mean concentration is greater than 60 µg/m³ may be susceptible to breaches of the hourly mean objective (hourly mean NO₂ concentration of 200 µg/m³ or more not to be exceeded more than 18 occasions per year). After bias adjustment, there are no sites with measured NO₂ concentrations greater than 60 µg/m³ in 2015.

¹¹ Air Quality Consultants (2007). Deriving NO₂ from NO_x for Air Quality Assessments of Roads.

Capabilities on project:
Environment

4.3.2 Seasonal Variation

The seasonal variation in NO₂ concentrations during 2015 are shown in Table 5 and Figure 2. Due to seasonal variations in the bias adjustment that can occur at diffusion tube sites, the results that have been presented are the raw concentrations with no bias adjustment applied.

The highest mean concentration occurred in October followed by September and then February at roadside sites. For urban background sites, the highest mean concentrations were measured during October and then January and February. Mean NO₂ concentrations were lowest in December, May and July for all site types.

Table 5 Monthly Mean NO₂ Concentrations in Lewisham, 2015 (µg/m³; Unadjusted)

Site Type	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
All Sites	41.1	41.1	38.8	38.4	30.2	33.7	32.6	36.6	40.6	46.0	38.1	28.8
Roadside	45.0	45.9	45.0	44.7	36.3	40.5	38.9	43.8	47.8	52.7	41.4	32.1
Urban Background	35.4	34.1	29.6	29.4	21.4	23.0	23.0	26.6	30.2	35.9	32.5	23.7

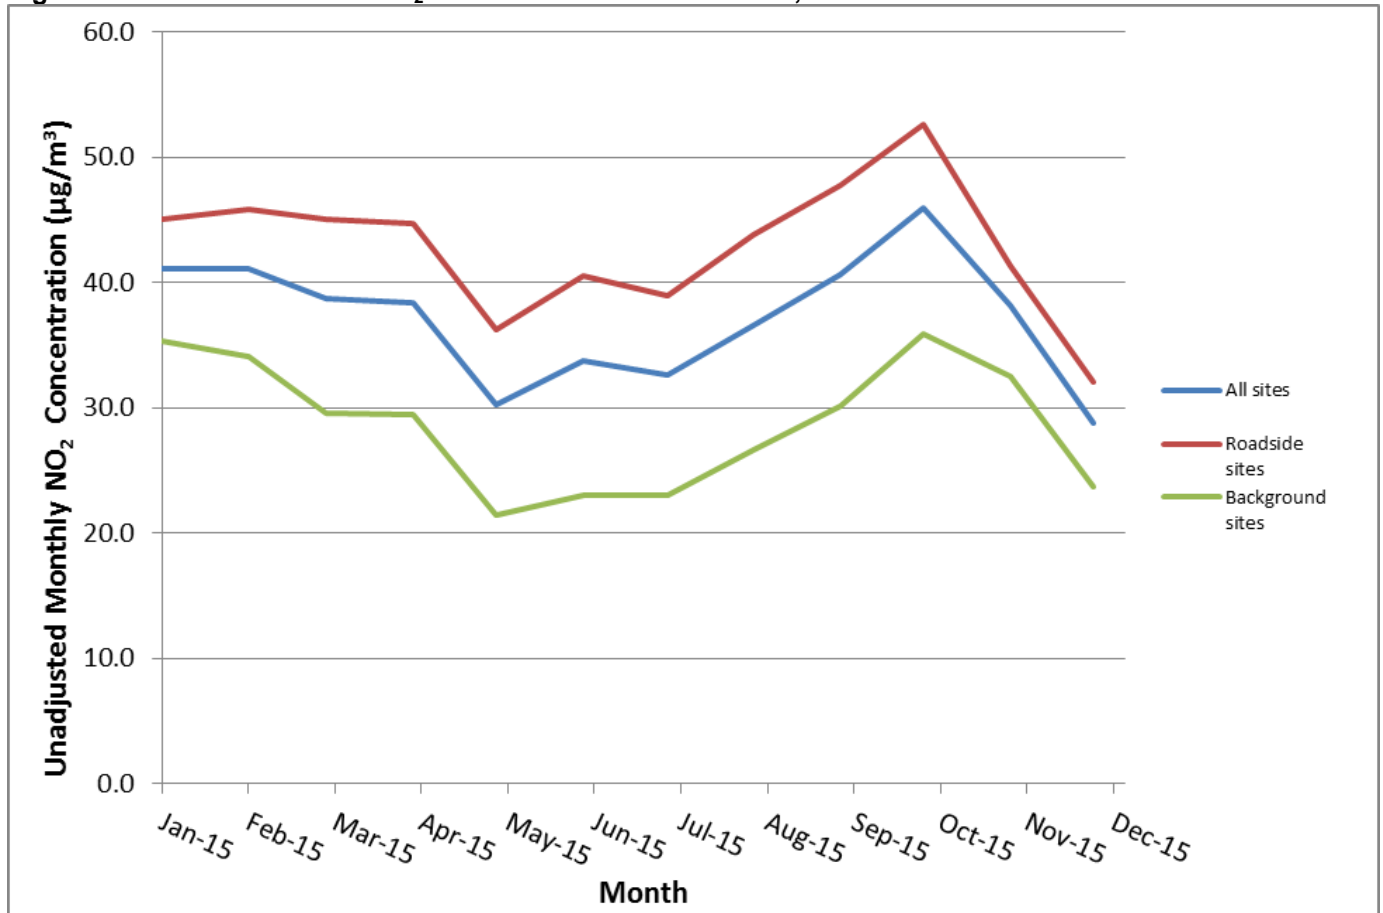

Table 6 Unadjusted Winter and Summer Period Mean Concentrations in Lewisham, 2015

Site Type	Winter Mean Concentration (October – March) (µg/m ³)	Summer Mean Concentration (April – September) (µg/m ³)	Ratio Winter : Summer
All Sites	39.0	35.4	1.1
Roadside	43.7	42.0	1.0
Urban Background	31.9	25.6	1.2

Table 6 shows that the ratio of winter to summer mean NO₂ concentration was 1.0 for roadside sites, indicating mean concentrations were similar in the winter and summer periods. The urban background sites display a higher winter: summer ratio compared to roadside sites indicating higher mean concentrations in winter than in summer periods. The value was 1.2 in 2015. For all sites, collectively, the ratio of winter to summer mean NO₂ concentration was 1.1.

Capabilities on project:
Environment

Figure 2: Seasonal Trend of NO₂ Concentrations in Lewisham, 2015

4.4 Historical Trends

Table 7 summarises the results of the Lewisham Tube Network by site type from 2012 to 2015, results for each site in 2015 are detailed in Appendix B. These results have been bias adjusted and the factors can be found in Appendix C Table 9. Measurements from the past year showed a decrease in annual mean NO₂ concentration across the network between 2014 and 2015 when considering the national bias adjusted concentrations, for which the national bias adjustment factors in both years were very similar. Considering just the local bias adjustment factor, NO₂ concentrations increased in 2015 relative to 2014, although as previously discussed, the local bias adjustment factor is higher than in previous years.

5 Conclusions

The main conclusions of the 2015 Lewisham Diffusion Tube Network study are:

- The mean NO₂ concentration for the whole network, based on local bias adjustment factor was 37.7 µg/m³ or 35.1 µg/m³ based on the national bias adjustment factor.

NO₂ concentrations were greatest at roadside monitoring locations, followed by urban background sites. The highest annual mean NO₂ concentration in 2015 was measured at site LWS017 (9 Baring Road). The mean concentration was 58.6 µg/m³ based on local bias adjustment factor, or 54.6 µg/m³ using the national bias adjustment factor. The second highest annual mean NO₂ concentration occurred at LWS016 at Montpelier Value with a value of 57.1 µg/m³ after applying the local bias adjustment factor or 53.2 µg/m³ – national bias adjusted.

- The mean roadside NO₂ concentration across the network was 43.5 µg/m³, based on the local bias adjustment factor, or 40.5 µg/m³ based on the national bias adjustment factor, and the mean urban background concentration was 29.3 µg/m³ using the local bias adjustment factor or 27.3 µg/m³ using the national bias adjustment factor.
- Results based on the local adjustment factor show that 14 diffusion tube locations recorded annual mean NO₂ concentrations exceeding the annual mean NO₂ objective of 40 µg/m³. Results obtained after applying the national bias adjustment factor show that 12 sites exceeded the annual mean NO₂ objective.

Appendix C: Diffusion Tube Bias Adjustment

A local bias adjustment factor was calculated in order to apply bias correction to the raw diffusion tube results for 2015. Triplicate tubes were co-located alongside the continuous NO₂ monitoring sites in New Cross Road (LW2), and this site has been used to calculate the bias adjustment factor 2015.

The continuous monitoring site listed above is part of the London Air Quality Network (LAQN reference is given in brackets). NO₂ concentration data from the continuous monitoring sites between 07/01/2015 and 05/01/2016 to cover the period of diffusion tube monitoring was collated. Period mean NO₂ concentrations were calculated for each diffusion tube exposure period during 2015. Data capture statistics for the same periods were also determined.

The continuous monitoring data and raw triplicate tube concentrations were inputted into the Bias Adjustment Calculator tool to calculate bias adjustment factors

The bias adjustment calculations for the monitoring site are shown in Figure 4. Table 9 provides a summary of the bias factor calculated for the site, and the comparison with national bias adjustment factors for the past years are also shown.

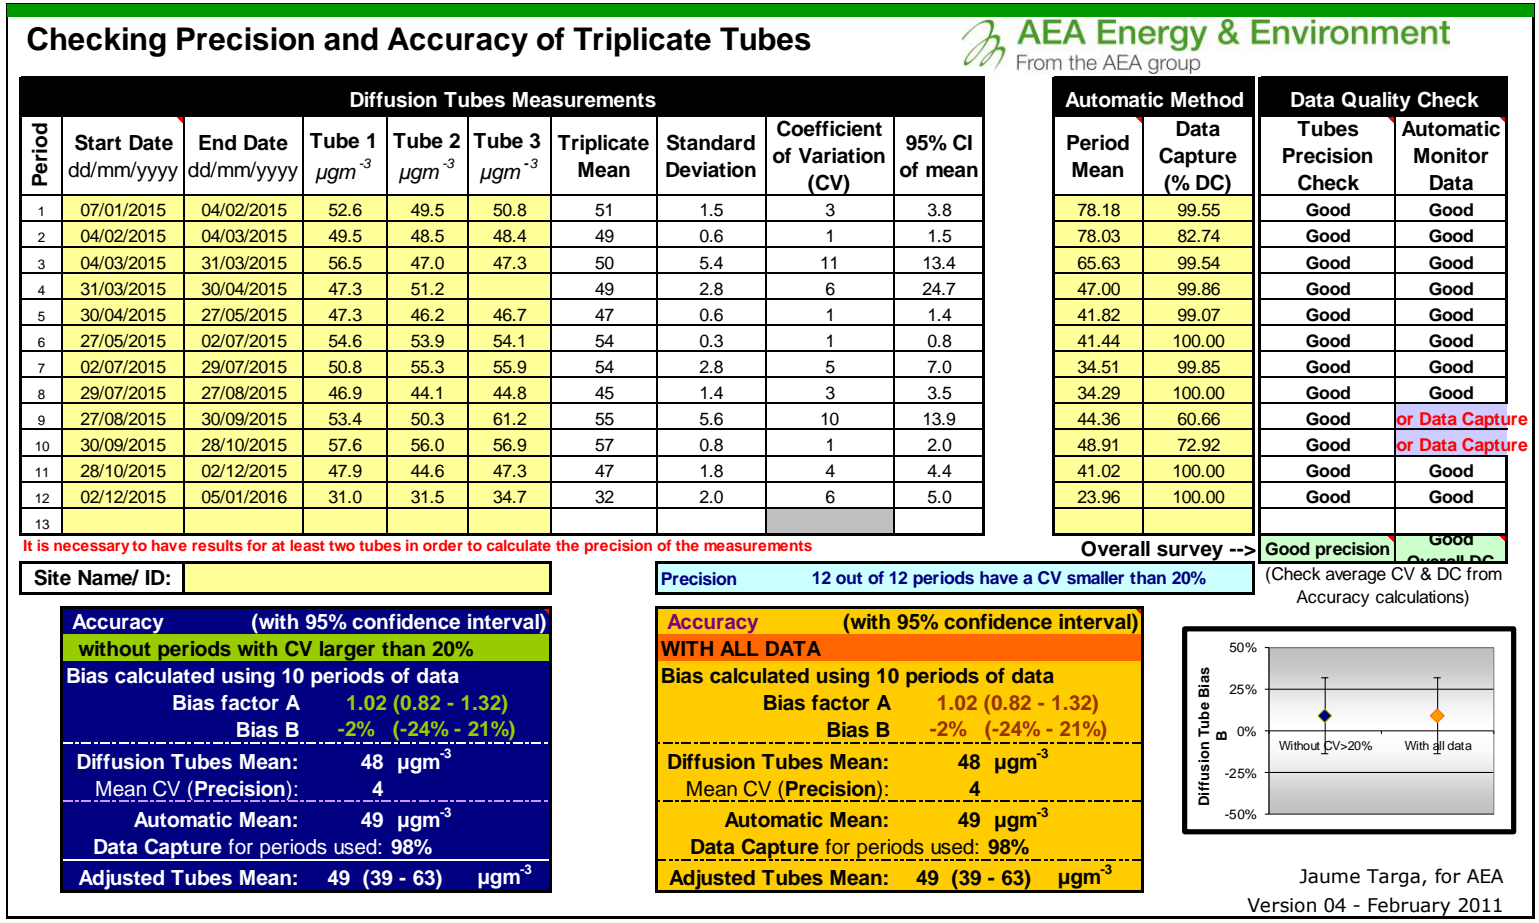

Table 9 Summary of Local and National Bias Adjustment Factors for Lewisham NO₂ Diffusion Tube Surveys, 2009 to 2015

Year	Mean Local Factor	National Factor ^a
2009	0.84	0.97
2010	0.69	1.03
2011	0.59	0.95
2012	0.79	1.01
2013	0.93	1.00
2014	0.82	0.97
2015	1.02	0.95

Notes: ^a National factor obtained from Bias Adjustment Factor spreadsheet³ version 03/16 based on Gradko as the analysing laboratory using the 50% TEA in acetone method;

National Diffusion Tube Bias Adjustment Factor Spreadsheet							Spreadsheet Version Number: 03/16				
Follow the steps below in the correct order to show the results of relevant co-location studies							This spreadsheet will be updated at the end of June 2016				
Data only apply to tubes exposed monthly and are not suitable for correcting individual short-term monitoring periods							This spreadsheet will be updated every few months: the factors may therefore be subject to change. This should not discourage their immediate use.				
Whenever presenting adjusted data, you should state the adjustment factor used and the version of the spreadsheet							LAQM Helpdesk Website				
The LAQM Helpdesk is operated on behalf of Defra and the Devolved Administrations by Bureau Veritas, in conjunction with contract partners AECOM and the National Physical Laboratory.							Spreadsheet maintained by the National Physical Laboratory. Original compiled by Air Quality Consultants Ltd.				
Step 1:	Step 2:	Step 3:	Step 4:								
Select the Laboratory that Analyses Your Tubes from the Drop-Down List	Select a Preparation Method from the Drop-Down List	Select a Year from the Drop-Down List	Where there is only one study for a chosen combination, you should use the adjustment factor shown with caution. Where there is more than one study, use the overall factor ³ shown in blue at the foot of the final column.								
If a laboratory is not shown, we have no data for this laboratory.	If a preparation method is not shown, we have no data for this method at this laboratory.	If a year is not shown, we have no data ²	If you have your own co-location study then see footnote ⁴ . If uncertain what to do then contact the Local Air Quality Management Helpdesk at LAQMhelpdesk@uk.bureauveritas.com or 0800 0327953
